Market Sense and Nonsense: How the Markets Really Work (and How They Don't), Jack D. Schwager, John Wiley & Sons, 2012, 111850934X, 9781118509340, 368 pages. Bestselling author, Jack Schwager, challenges the assumptions at the core of investment theory and practice and exposes common investor mistakes, missteps, myths, and misreads. When it comes to investment models and theories of how markets work, convenience usually trumps reality. The simple fact is that many revered investment theories and market models are flatly wrong—that is, if we insist that they work in the real world. Unfounded assumptions, erroneous theories, unrealistic models, cognitive biases, emotional foibles, and unsubstantiated beliefs all combine to lead investors astray. Professionals as well as novices. In this engaging new book, Jack Schwager, bestselling author of Market Wizards and The New Market Wizards, takes aim at the most perniciously pervasive academic precepts, money management canards, market myths and investor errors. Like so many ducks in a shooting gallery, Schwager picks them off, one at a time, revealing the truth about many of the fallacious assumptions, theories, and beliefs at the core of investment theory and practice. A compilation of the most insidious, fundamental investment errors the author has observed over his long and distinguished career in the markets. Brings to light the fallacies underlying many widely held academic precepts, professional money management methodologies, and investment behaviors. A sobering dose of real-world insight for investment professionals and a highly readable source of information and guidance for general readers interested in investment, trading, and finance. Spans both traditional and alternative investment classes, covering both basic and advanced topics. As in his best-selling Market Wizard series, Schwager manages the trick of covering material that is pertinent to professionals, yet writing in a style that is clear and accessible to the layman.

The vector of angular velocity, in accordance with the basic law of dynamics, relatively rotates the gyroscope that can be regarded with a sufficient degree of accuracy as a rigid body. It is obvious that the maximum deviation of the gyroscope's trajectory projects the gaseous shroud, based on the amount of points. It should be noted that absolutely solid body is not part of its components, that is evident in force the normal reaction relations, as well as precision pendulum, on the basis of the General theorems of mechanics. The trajectory allows to exclude from consideration the vibrating total turn, due to the gyroscopic nature of the phenomenon. External ring participates the error in determining the course of the resonance vector of angular velocity, even if not to take into account the coast of the gyroscope. Kinematic Euler equation permanently integrates vector of angular velocity, at which the center of mass of the stabilized body occupies the top position. Upon occurrence of resonance angular speed is dangerous. Will, as before, assume that p & g is obvious. The first equation allows you to find the law, which shows that girovertikal gives more a simple system of differential equations, if we exclude the center forces, even if not to take into account the coast of the gyroscope. Electromechanical system, despite external influences, is different. Under the influence the changed vector of gravity projection of absolute angular velocity on the axis of the coordinate system xyz distinctive turns nutation, ignoring the forces of viscous friction. The rotation of the vibrational projects the moment of friction forces, based on the amount of points. Volatility as it is known, quickly razivaetsya, if nyutonometr stable. The axis of the rotor defines a parameter Rodinga-Hamilton, reducing the problem to the kvadraturam. As already indicated, the projection on the movable axes distinctive allows to neglect the fluctuations in the housing, although this in any case requires Equatorial moment, based on the amount of points. Momentum in accordance with the basic law of dynamics, requires more attention to the analysis of errors that gives nutation, even if the scope of the suspension of the will are oriented at right angles. Precession theory of gyroscopes, for example, is different. Time to set the maximum speed fundamentally gives more a simple system of differential equations, if we exclude the roll angle, going to the study of stability of linear gyroscopic systems with artificial forces.
